Eighth Workshop on
BAYESIAN INFERENCE IN STOCHASTIC PROCESSES

Bayesian multi-resolution inference of stochastic models from partially observed data

Samuel Kou¹

¹ Department of Statistics, Harvard University, USA

Stochastic models, diffusion models in particular, are widely used in science, engineering and economics. Inferring the parameter values from data is often complicated by the fact that the underlying stochastic processes are only partially observed. Examples include inference of discretely observed diffusion processes and stochastic volatility models. Likelihood based inference faces the difficulty that the likelihood is usually not available even numerically. Conventional approach discretizes the stochastic model to approximate the likelihood. In order to have desirable accuracy, one has to use highly dense discretization. However, dense discretization usually imposes unbearable computation burden. In this talk we will introduce the framework of Bayesian multi-resolution inference to address this difficulty. By working on different resolution (discretization) levels simultaneously and by letting the resolutions talk to each other, we substantially improve not only the computational efficiency, but also the estimation accuracy. We will illustrate the strength of the multi-resolution approach by examples.

Keywords:

Data augmentation; multi-resolution sampler; multi-resolution extrapolation.
